

Apple vs. PC

One of the perennial disagreements in the modern world – and one that raises a disturbing degree of passion – is that between fans of PCs and devotees of Apple computers. Apple users, in particular, tend to be desperately vocal in their support of their preferred technology; in return, PC fans often look down on those who exclusively use Apple products.

The primary selling point of Apple's technology is that it is seamless – the user buys the hardware, operating system, and even browser from only one company – and it is effortlessly functional. In contrast, PCs are made by a thousand different dealers in a million configurations, with a choice of operating systems and software from more people than you can shake a stick at.

This difference is at the core of the Apple/PC debate. Apple's systems, though less powerful, are easy to use and have a coherent, (usually) problem-free style. PCs, on the other hand, are more powerful and flexible, but, as a direct result of this, are more complex and have more flaws. Frankly, the controversy is pointless. Neither system is better, but both systems are better for some people.
